第1章　LeetCode Hot 100

Goals to Achieve

    1. unordered_map.

§ 1.1 两数之和unordered_map

> **HOT100 1.1　问题描述**
>
> 给定一个整数数组**nums** 和一个目标值**target**, 请你在该数组中找出和为目标值的那两个整数, 并返回他们的数组下标. 你可以假设每种输入只会对应一个答案. 但是, 你不能重复利用这个数组中同样的元素.
>
> 示例: 给定nums = [2, 7, 11, 15], target = 9; 因为nums[0] + nums[1] = 2 + 7 = 9;
>
> 所以返回[0, 1]
>
> `https://leetcode-cn.com/problems/two-sum`

1.1.1 解题思路

这里用c++的unordered_map来解决, unordered_map内部是一个关联容器, 采用hash 表结构, 有快速检索的功能.

哈希表是通过key关键字直接访问对应value值的数据结构. 特点是键和值一一对应, 查找时间复杂度**O(1)**.

Example_1: unordered_map插入, 迭代遍历.

unordered_map example_1 code

```cpp
#include <iostream>
#include <unordered_map>
#include <string>
using namespace std;
int main()
```

```
6    {
7        unordered_map<string, double> umap;
8        umap["PI"] = 3.14;
9        umap.insert(make_pair("a", 2.1));
10
11       // find in umap
12       string key = "PI";
13       if (umap.find(key) == umap.end())
14           cout << "cannot find PI" << endl;
15       else
16           cout << "find " << umap.find(key)->first << " = " << umap.find(key)->second << endl;
17
18       // iterator of umap
19       cout << "entire unorded_map is:"<<endl;
20       unordered_map<string, double>::iterator itr;
21       for (itr = umap.begin(); itr != umap.end(); ++itr)
22           cout << " (" << itr->first << "," << itr->second << ") " << endl;
23       system("pause");
24       return 0;
25   }
```

```
output:
find PI = 3
all elements are:
(PI,3.14)
(a,2.1)
```

Example_2: 利用unordered_map输出一段文字中重复单词的个数

unordered_map example_2 code

```
1    #include <iostream>
2    #include <unordered_map>
3    #include <string>
4    #include <sstream>
5
6    using namespace std;
7
8    void printWordFreq(const string& str)
9    {
10       unordered_map<string, int> wordFreq;
11       string word;
```

```
12        stringstream ss(str);
13        while (ss >> word)
14            wordFreq[word]++;
15
16        cout << "all elements are:" << endl;
17        for (auto u : wordFreq)
18            cout << "(" << u.first << "," << u.second << ")" << endl;
19    }
20
21    int main()
22    {
23        string str = "studies very very hard";
24        printWordFreq(str);
25        return 0;
26    }
```

output:
all elements are:
(studies, 1)
(very, 2)
(hard, 1)

1.1.2 解题代码

```
1    #include <iostream>
2    #include <unordered_map>
3    #include <vector>
4    using namespace std;
5
6    vector<int> twoSum(vector<int>& nums, int target)
7    {
8        unordered_map<int, int> map;
9        vector<int> result={};
10       int n = (int)nums.size();
11       for(int i = 0; i < n; ++i) {
12           auto p = map.find(target−nums[i]);
13           if(p != map.end()) {
14           result.push_back(p−>second);
15           result.push_back(i);
```

```
16          }
17      map[nums[i]] = i;
18      }
19      return result;
20  }
21
22  int main()
23  {
24      vector< int > nums = {2,7,11,15};
25      vector<int> result;
26      result = twoSum(nums,9);
27      cout<<"["<<result[0] << "," <<result[1]<<"]"<<endl;
28      return 0;
29  }
```

§1.2 两数相加linked list

<div style="background:#cceeff">

HOT100 1.2   问题描述

给出两个非空的链表用来表示两个非负的整数. 其中, 它们各自的位数是按照逆序的方式存储的, 并且它们的每个节点只能存储一位数字. 如果, 我们将这两个数相加起来, 则会返回一个新的链表来表示它们的和.

您可以假设除了数字0之外, 这两个数都不会以0开头.

示例: 输入$(2->4->3)+(5->6->4)$, 输出: $7->0->8$, 原因: $342+465=807$

https://leetcode-cn.com/problems/add-two-numbers

</div>

1.2.1 解题思路

这里用c++ 链表来解决

Example_1: 创建链表并初始化

linked list example_1 code

```
1  #include <iostream>
2
3  using namespace std;
4
5  class Node{
```

```cpp
public:
    int data;
    Node* next;
};

int main()
{
    Node* head = nullptr;
    Node* second = nullptr;
    Node* third = nullptr;

    head = new Node();
    head->data = 1;

    second = new Node();
    second->data = 2;

    third = new Node();
    third->data = 3;

    cout << head->data << " " << second->data << " " << third->data << endl;

    delete head;
    delete second;
    delete third;
    return 0;
}
```

output:
1 2 3

Example_2: 打印链表中的所有元素

linked list example_2 code

```cpp
#include <iostream>

using namespace std;

class Node{
public:
    int data;
```

```cpp
8        Node* next;
9    };
10
11   void PrintLinkedList(Node* head)
12   {
13       Node* temp = head;
14       while (temp != nullptr) {
15           cout << temp->data << " ";
16           temp = temp->next;
17       }
18       cout << endl;
19   }
20
21   int main()
22   {
23       Node* head = nullptr;
24       Node* second = nullptr;
25       Node* third = nullptr;
26
27       head = new Node();
28       second = new Node();
29       third = new Node();
30
31       head->data = 1;
32       head->next = second;
33
34       second->data = 2;
35       second->next = third;
36
37       third->data = 3;
38       third->next = nullptr;
39
40
41       PrintLinkedList(head);
42
43       delete head;
44       delete second;
45       delete third;
46       return 0;
47   }
```

output:
1 2 3

Example_3: 链表插入节点

linked list example_3 code

```cpp
#include <iostream>

using namespace std;

class Node{
public:
    int data;
    Node* next;
};

// 在链表前面插入节点
void push(Node** head_ref, int newData)
{
    Node* newNode = new Node();
    newNode->data = newData;
    newNode->next = (*head_ref);
    (*head_ref) = newNode;
}

// 在节点后面插入节点
void insertAfter(Node** prev_node, int newData)
{
    if ((*prev_node) == nullptr) {
        cout << "the previous node cannot be nullptr" << endl;
        return;
    }

    Node* newNode = new Node();
    newNode->data = newData;
    newNode->next = (*prev_node)->next;
    (*prev_node)->next = newNode;
}

// 在尾节点后插入节点
```

```cpp
void append(Node** head_ref, int newData)
{
    Node* newNode = new Node();
    newNode->data = newData;
    newNode->next = nullptr;
    if ((*head_ref) == nullptr) {
        (*head_ref) = newNode;
        return;
    }

    Node* move = (*head_ref);
    while (move->next != nullptr) {
        move = move->next;
    }
    move->next = newNode;
}

//打印链表
void PrintLinkedList(Node* head)
{
    Node* temp = head;
    while (temp != nullptr) {
        cout << temp->data << "  ";
        temp = temp->next;
    }
    cout << endl;
}

void destroyLinkedList(Node** head_ref) {
    Node* move = (*head_ref);
    Node* next = nullptr;
    while (move != nullptr) {
        next = move->next;
        delete move;
        move = next;
    }
    (*head_ref) = nullptr;
}

int main()
```

```
75  {
76      Node* head = nullptr;
77
78      append(&head, 6);
79
80      push(&head, 7);
81
82      push(&head, 1);
83
84      append(&head, 4);
85
86      insertAfter(&(head->next), 8);
87
88      cout << "linked list is: ";
89      PrintLinkedList(head);
90      destroyLinkedList(&head);
91      return 0;
92  }
```

output:
linked list is: 1 7 8 6 4

1.2.2 解题代码

```
1   #include <iostream>
2   using namespace std;
3
4   struct ListNode {
5       int val;
6       ListNode *next;
7       ListNode(int x) : val(x), next(NULL) {}
8   };
9
10  ListNode* addTwoNumbers(ListNode* l1, ListNode* l2) {
11      int len1 = 1;//记录的长度l1
12      int len2 = 1;//记录的长度l2
13      ListNode* p = l1;
14      ListNode* q = l2;
15      while (p->next != NULL)//获取的长度l1
```

```
16          {
17              len1++;
18              p = p−>next;
19          }
20          while (q−>next != NULL)//获取的长度l2
21          {
22              len2++;
23              q = q−>next;
24          }
25          if (len1 > len2)//较长，在末尾补零l1l2
26          {
27              for (int i = 1; i <= len1 − len2; i++)
28              {
29                  q−>next = new ListNode(0);
30                  q = q−>next;
31              }
32          }
33          else//较长，在末尾补零l2l1
34          {
35              for (int i = 1; i <= len2 − len1; i++)
36              {
37                  p−>next = new ListNode(0);
38                  p = p−>next;
39              }
40          }
41          p = l1;
42          q = l2;
43          bool count = false;//记录进位
44          ListNode∗ l3 = new ListNode(−1);//存放结果的链表
45          ListNode∗ w = l3;//的移动指针l3
46          int i = 0;//记录相加结果
47          while (p != NULL && q != NULL)
48          {
49              i = count + p−>val + q−>val;
50              w−>next = new ListNode(i % 10);
51              count = i >= 10 ? true : false;
52              w = w−>next;
53              p = p−>next;
54              q = q−>next;
55          }
```

```
56        if (count)//若最后还有进位
57        {
58            w->next = new ListNode(1);
59            w = w->next;
60        }
61        return l3->next;
62  }
63
64  void printLinkedList(ListNode* head)
65  {
66        ListNode* move = head;
67        while (move != nullptr) {
68            cout << move->val << "  ";
69            move = move->next;
70        }
71  }
72
73  int main()
74  {
75  #if 1
76        ListNode* l1 = new ListNode(2);
77        ListNode* l1_1 = new ListNode(4);
78        ListNode* l1_2 = new ListNode(3);
79
80        l1->next = l1_1;
81        l1_1->next = l1_2;
82
83
84        ListNode* l2 = new ListNode(5);
85        ListNode* l2_1 = new ListNode(6);
86        ListNode* l2_2 = new ListNode(4);
87        l2->next = l2_1;
88        l2_1->next = l2_2;
89  #endif
90
91  #if 0
92        ListNode* l1 = new ListNode(5);
93        ListNode* l2 = new ListNode(5);
94  #endif
95
```

```
96      ListNode∗ result = addTwoNumbers(l1, l2);
97      printLinkedList(result);
98      return 0;
99   }
```

output:
7 0 8

§1.3　无重复字符的最长子串(double pointer algorithm, set)

> **HOT100 1.3　问题描述**
>
> 给定一个字符串, 请你找出其中不含有重复字符的最长子串的长度.
>
> **示例1**:
>
> 输入: "abcabcb"
>
> 输出: 3
>
> 解释: 因为无重复字符的最长子串是"abc", 所以其长度为3.
>
> **示例2**:
>
> 输入: "bbbbb"
>
> 输出: 1
>
> 解释: 因为无重复字符的最长子串是"b", 所以其长度为1.
>
> **示例3**:
>
> 输入: "pwwkew"
>
> 输出: 3
>
> 解释: 因为无重复字符的最长子串是"wke", 所以其长度为3. 请注意, 你的答案必须是子串的长度, "pwke"是一个子序列, 不是子串.
>
> https://leetcode-cn.com/problems/longest-substring-without-repeating-characters

1.3.1　解题思路

https://cloud.tencent.com/developer/article/1377650

这道题主要用到思路是: 滑动窗口

什么是滑动窗口?

　　其实就是一个队列, 比如例题中的abcabcbb, 进入这个队列(窗口)为abc满足题目要求, 当再进入a, 队列变成了abca, 这时候不满足要求. 所以, 我们要移动这个队列!

　　如何移动?

　　我们只要把队列的左边的元素移出就行了, 直到满足题目要求!

　　一直维持这样的队列, 找出队列出现最长的长度时候, 求出解!

　　时间复杂度: **O(n)**

1.3.2 解题代码

```cpp
#include <iostream>
#include <string>
#include <unordered_set>
#include <algorithm> // max, min

using namespace std;

int lengthOfLongestSubstring(string s) {
    if (s.size() == 0) return 0;
    unordered_set<char> lookup;
    int maxStr = 0;
    int left = 0;
    for (int i = 0; i < s.size(); i++) {
        while (lookup.find(s[i]) != lookup.end()) {
            lookup.erase(s[left]);
            left++;
        }
        maxStr = max(maxStr, i - left + 1);
        lookup.insert(s[i]);
    }
    return maxStr;
}

int main()
{
    string str = "abcabcb";
    cout << lengthOfLongestSubstring(str) << endl;
    return 0;
}
```

output:

3

§1.4 寻找两个有序数组的中位数(二分查找|折半查找算法)

HOT100 1.4　问题描述

给定两个大小为m和n的有序数组nums1和nums2.

请你找出这两个有序数组的中位数, 并且要求算法的时间复杂度为**O(log(m + n))**.

你可以假设nums1和nums2不会同时为空.

示例1:

nums1 = [1, 3]

nums2 = [2]

则中位数是2.0

示例2:

nums1 = [1, 2]

nums2 = [3, 4]

则中位数是(2 + 3)/2 = 2.5

https://leetcode-cn.com/problems/median-of-two-sorted-arrays

1.4.1 解题思路

用二分查找算法, 也叫做折半查找算法.

Example_1: 二分查找

二分查找算法*example_1 code*

```
// 二分查找折半查找|
int search(int arr[], int key, int left, int right)
{
    while (left <= right)
    {
        int mid = left + (right − left) / 2;
        if (key < arr[mid])
            right = mid − 1;
        else if (key > arr[mid])
            left = mid + 1;
```

```cpp
            else
                return mid;
        }
    return −1;
}

int main()
{
    int arr[] = { 0,2 ,3,4};
    int value = 3;

    // left Index of the array
    int left = 0;

    // right Index of the array
    int right = sizeof(arr) / sizeof(arr[0]) − 1;

    cout << "left: " << left << ", right: " << right << endl;

    int ret = search(arr, value, left, right);
    if (ret == −1)
        printf("cannot find the value");
    else
        printf("found the value, the index is: %d\n", ret);
    system("pause");
    return 0;
}
```

output:
left: 0, right: 3 found the value, the index is: 2

第2章 深度学习

Goals to Achieve

1. pytorch basics

2. pytorch projects

§2.1 Pytorch

打印模型结构

pip install torchsummary

summary(model, (3, 32, 32))

print(model)
